

Essential Mathematical Methods for Engineers

Lecture 6:
Linear algebra 1

Linear Algebra

- this lecture is based upon
 - “*Introduction to Linear Algebra*,”
Strang, Wellesley Cambridge Press
2009
 - several copies in the library

Outline

- solving linear equations
 - row and column pictures
 - elimination
 - the inverse matrix
 - factorisation
- vector spaces and subspaces
 - column space
 - nullspace
 - rank and row reduced form
 - special solutions
 - complete solution
 - independence, basis and dimension
 - the four fundamental subspaces
 - the first fundamental theorem of linear algebra

Linear algebra

3

Solving linear equations

Vectors and linear equations

$$\begin{aligned} x - 2y &= 1 \\ 3x + 2y &= 11 \end{aligned}$$

$$x \begin{bmatrix} 1 \\ 3 \end{bmatrix} + y \begin{bmatrix} -2 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 \\ 11 \end{bmatrix}$$

- row picture

- column picture

$$\begin{bmatrix} 1 & -2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 1 \\ 11 \end{bmatrix} \quad \text{▪ matrix equation}$$

Linear algebra

4

Three equations in three unknowns

$$\begin{aligned}x + 2y + 3z &= 6 \\2x + 5y + 2z &= 4 \\6x - 3y + z &= 2\end{aligned}$$

the **row picture** shows three planes meeting at a single point

Linear algebra

5

Three equations in three unknowns

the **column picture** combines three columns to produce the fourth

$$x \begin{bmatrix} 1 \\ 2 \\ 6 \end{bmatrix} + y \begin{bmatrix} 2 \\ 5 \\ -3 \end{bmatrix} + z \begin{bmatrix} 3 \\ 2 \\ 1 \end{bmatrix} = \begin{bmatrix} 6 \\ 4 \\ 2 \end{bmatrix}$$

whatever the approach, the solution is $(x, y, z) = (0, 0, 2)$

Linear algebra

6

Elimination

$$\begin{array}{r} x - 2y = 1 \\ 3x + 2y = 11 \end{array} \quad \Rightarrow \quad \begin{array}{r} x - 2y = 1 \\ 8y = 8 \end{array}$$

- elimination produces an **upper triangular system**
 - with the same solution
 - solved by back substitution

Linear algebra

7

Elimination

$$\begin{array}{r} x - 2y = 1 \\ 3x + 2y = 11 \end{array} \quad \Rightarrow \quad \begin{array}{r} x - 2y = 1 \\ 8y = 8 \end{array}$$

- concept of pivots
 - to solve n equations we need n pivots
- three cases where n pivots *might* not be possible
 - no solution
 - infinitely many solutions
 - temporary failure – solved with row exchange

Linear algebra

8

Elimination

case 1: no solution

$$\begin{array}{r} x - 2y = 1 \\ 3x - 6y = 11 \end{array} \quad \Rightarrow \quad \begin{array}{r} x - 2y = 1 \\ 0y = 8 \end{array}$$

Row picture

Column picture

Linear algebra

9

Elimination

case 2: infinitely many solutions

$$\begin{array}{r} x - 2y = 1 \\ 3x - 6y = 3 \end{array} \quad \Rightarrow \quad \begin{array}{r} x - 2y = 1 \\ 0y = 0 \end{array}$$

Row picture

Column picture

Linear algebra

10

Elimination

- case 3: temporary failure

$$\begin{array}{l} 0x + 2y = 4 \\ 3x - 2y = 5 \end{array} \quad \Rightarrow \quad \begin{array}{l} 3x - 2y = 5 \\ 2y = 4 \end{array}$$

by interchanging rows we obtain an upper triangular system with 2 pivots and one unique solution

- case 1 and 2 are singular – no second pivot
 - no solution, or infinitely many solutions
- case 3 is nonsingular – two unique pivots
 - one unique solution

Linear algebra

11

Elimination

Example: you should have no difficulty extending this to higher order systems, e.g.:

$$\begin{array}{l} 2x + 4y - 2z = 2 \\ 4x + 9y - 3z = 8 \\ -2x - 3y + 7z = 10 \end{array} \quad \Rightarrow \quad \begin{array}{l} 2x + 4y - 2z = 2 \\ 1y + 1z = 4 \\ 4z = 8 \end{array}$$

Linear algebra

12

Elimination using matrices

$$Ax = b$$

$$\begin{array}{rcl} 2x + 4y - 2z & = & 2 \\ 4x + 9y - 3z & = & 8 \\ -2x - 3y + 7z & = & 10 \end{array} \quad \begin{bmatrix} 2 & 4 & -2 \\ 4 & 9 & -3 \\ -2 & -3 & 7 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 2 \\ 8 \\ 10 \end{bmatrix}$$

has solution

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} -1 \\ 2 \\ 2 \end{bmatrix}$$

- Ax is a combination of the columns of A

$$Ax = (-1) \begin{bmatrix} 2 \\ 4 \\ -2 \end{bmatrix} + 2 \begin{bmatrix} 4 \\ 9 \\ -3 \end{bmatrix} + 2 \begin{bmatrix} -2 \\ -3 \\ 7 \end{bmatrix} = \begin{bmatrix} 2 \\ 8 \\ 10 \end{bmatrix}$$

Linear algebra

13

Elimination using matrices

- we can perform elimination using matrices
- the matrix which performs the first step of the elimination is

$$E = \begin{bmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

and correspondingly

$$EA = \begin{bmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 2 & 4 & -2 \\ 4 & 9 & -3 \\ -2 & -3 & 7 \end{bmatrix} = \begin{bmatrix} 2 & 4 & -2 \\ 0 & 1 & 1 \\ -2 & -3 & 7 \end{bmatrix}$$

so we have that $EAx = Eb = [2 \ 4 \ 10]^T$

- note the 2D associative law: $A(BC) = (AB)C$
 - this is not commutative: $AB \neq BA$

Linear algebra

14

Row exchange

- P matrices exchange or permute rows
 - i.e. when there is a zero in the pivot position

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix} = \begin{bmatrix} 1 \\ 5 \\ 3 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} 2 & 4 & 1 \\ 0 & 0 & 3 \\ 0 & 6 & 5 \end{bmatrix} = \begin{bmatrix} 2 & 4 & 1 \\ 0 & 6 & 5 \\ 0 & 0 & 3 \end{bmatrix}$$

needed
for case 3

Linear algebra

15

The augmented matrix

- E and P matrices can be applied to A and b separately
 - also to the augmented matrix A'

$$A' = [A \ b] = \begin{bmatrix} 2 & 4 & -2 & 2 \\ 4 & 9 & -3 & 8 \\ -2 & -3 & 7 & 10 \end{bmatrix}$$

— and thus

$$EA' = \begin{bmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 2 & 4 & -2 & 2 \\ 4 & 9 & -3 & 8 \\ -2 & -3 & 7 & 10 \end{bmatrix} = \begin{bmatrix} 2 & 4 & -2 & 2 \\ 0 & 1 & 1 & 4 \\ -2 & -3 & 7 & 10 \end{bmatrix}$$

- each row of E acts on A' to give a row of EA'
- E acts on each column of A' to give a column of EA'

Linear algebra

16

Rows and Columns of AB

- column picture
 - A multiplies each column of B and gives a column of AB
 - each column of AB is a combination of the columns of A
- row picture
 - each row of A multiplies the whole of matrix B to give a row of AB
 - each row of AB is a combination of the rows of B
- note the row-column picture AND the column-row picture

Linear algebra

17

Laws for matrix operations

Addition

- commutative

$$A + B = B + A$$
- distributive

$$c(A + B) = cA + cB$$
- associative

$$A + (B + C) = (A + B) + C$$

Multiplication

- commutative

$$AB \neq BA$$
- distributive

$$C(A + B) = CA + CB$$

$$(A + B)C = AC + BC$$
- associative

$$A(BC) = (AB)C$$

Matrix powers

$$A^p = AAA \cdots A \quad (p \text{ factors}) \quad (A^p)(A^q) = A^{p+q} \quad (A^p)^q = A^{pq}$$

normal rules apply when p or q are negative A^{-1} is the inverse

Linear algebra

18

Inverse matrix

$$A^{-1}Ax = A^{-1}b \quad \text{gives} \quad x = A^{-1}b$$

- but it's not needed to solve $Ax=b$
 - we can just use elimination
 - still of interest and a fundamental property of matrices
- inverse exists if there is a matrix A^{-1} such that

$$A^{-1}A = I \quad \text{or} \quad AA^{-1} = I$$

or if there are n pivots

Linear algebra

19

Inverse matrix

- the inverse is unique since if $BA=I$ and $AC=I$
 $B(AC) = (BA)C$ gives $BI = IC$ or $B = C$
- if A is invertible then the only solution to $Ax=b$ is $x=A^{-1}b$
 Multiply $Ax=b$ by A^{-1} then $x = A^{-1}Ax = A^{-1}b$
- if there is a non-zero vector x such that $Ax=0$ then A is not invertible – if A is invertible the only solution to $Ax=0$ is $x=0$
- a 2×2 matrix is invertible only if $ad-bc \neq 0$

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}^{-1} = \frac{1}{ad-bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

- for diagonal matrices

$$\text{If } A = \begin{bmatrix} d_1 & & \\ & \ddots & \\ & & d_n \end{bmatrix} \text{ then } A^{-1} = \begin{bmatrix} 1/d_1 & & \\ & \ddots & \\ & & 1/d_n \end{bmatrix}$$

Linear algebra

20

Inverse of a product

- if A and B are invertible then

$$(AB)^{-1} = B^{-1}A^{-1}$$

since

$$B^{-1}A^{-1}AB = B^{-1}IB = B^{-1}B = I$$

- similarly

$$(ABC)^{-1} = C^{-1}B^{-1}A^{-1}$$

Linear algebra

21

Inverse by Gauss-Jordan Elimination

- we try to solve $AA^{-1}=I$ one column at a time

$$AA^{-1} = A[x_1 \ x_2 \ x_3] = [e_1 \ e_2 \ e_3] = I$$

- we have only to solve $Ax_n=e_n$ to obtain A^{-1} – we solve 3 systems of equations
- using an augmented matrix $[A \ I]$ we can determine $[I \ A^{-1}]$ and solve all n equations together
 - upper triangular form through Gaussian elimination

$$\begin{bmatrix} 2 & -1 & 0 & 1 & 0 & 0 \\ -1 & 2 & -1 & 0 & 1 & 0 \\ 0 & -1 & 2 & 0 & 0 & 1 \end{bmatrix} \Rightarrow \begin{bmatrix} 2 & -1 & 0 & 1 & 0 & 0 \\ 0 & \frac{3}{2} & -1 & \frac{1}{2} & 1 & 0 \\ 0 & 0 & \frac{4}{3} & \frac{1}{3} & \frac{2}{3} & 1 \end{bmatrix}$$

which we could solve by back substitution

Linear algebra

22

Inverse by Gauss-Jordan Elimination

- Jordan continued to reduced echelon form

$$\begin{bmatrix} 2 & -1 & 0 & 1 & 0 & 0 \\ 0 & \frac{3}{2} & -1 & \frac{1}{2} & 1 & 0 \\ 0 & 0 & \frac{4}{3} & \frac{1}{3} & \frac{2}{3} & 1 \end{bmatrix} \Rightarrow \begin{bmatrix} 2 & 0 & 0 & \frac{3}{2} & 1 & \frac{1}{2} \\ 0 & \frac{3}{2} & 0 & \frac{3}{4} & \frac{3}{2} & \frac{3}{4} \\ 0 & 0 & \frac{4}{3} & \frac{1}{3} & \frac{2}{3} & 1 \end{bmatrix}$$

and dividing rows by their pivots

$$\begin{bmatrix} 2 & 0 & 0 & \frac{3}{2} & 1 & \frac{1}{2} \\ 0 & \frac{3}{2} & 0 & \frac{3}{4} & \frac{3}{2} & \frac{3}{4} \\ 0 & 0 & \frac{4}{3} & \frac{1}{3} & \frac{2}{3} & 1 \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 0 & 0 & \frac{3}{4} & \frac{1}{2} & \frac{1}{4} \\ 0 & 1 & 0 & \frac{1}{2} & 1 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{1}{4} & \frac{1}{2} & \frac{3}{4} \end{bmatrix}$$

so that the inverse is

$$A^{-1} = \begin{bmatrix} \frac{3}{4} & \frac{1}{2} & \frac{1}{4} \\ \frac{1}{2} & 1 & \frac{1}{2} \\ \frac{1}{4} & \frac{1}{2} & \frac{3}{4} \end{bmatrix}$$

Linear algebra

23

Singular versus invertible

- an $n \times n$ matrix must have n pivots in order to be invertible
 - we can solve all the equations $Ax_i = e_i$ and the columns x_i give A^{-1}
 - then $AA^{-1} = I$

- elimination is really a long sequence of manipulations

$$(D^{-1} \dots E \dots P \dots E)A = I$$

where D^{-1} divides by the pivots

- this gives a left inverse such that $A^{-1}A = I$ - the same solution
- if there are not n pivots then A^{-1} does not exist

Linear algebra

24

LU factorisation

- a factorisation of A into the product of two triangular matrices

$$E_{21}A = \begin{bmatrix} 1 & 0 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ 6 & 8 \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 0 & 5 \end{bmatrix} = U$$

$$E_{21}^{-1}U = \begin{bmatrix} 1 & 0 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ 0 & 5 \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 6 & 8 \end{bmatrix} = A$$

or $LU=A$

- the L matrix includes the inverses of all the E matrices
- combining all the elimination matrices

$$A = (E^{-1} \dots P^{-1} \dots E^{-1})U$$

Linear algebra

25

LU factorisation

$$(E_{32}E_{31}E_{21})A = U \quad \text{becomes} \quad A = (E_{21}^{-1}E_{31}^{-1}E_{32}^{-1})U \quad \text{which is} \quad A = LU$$

- some points
 - every inverse matrix E^{-1} is lower triangular
 - its off diagonal entry ℓ_{ij} undoes the subtraction in E with $-\ell_{ij}$
 - the diagonals of E and E^{-1} contain 1
 - the product of the E 's is still lower triangular – this is L
 - each multiplier ℓ_{ij} goes directly into its i,j position unchanged in the product L
 - when a row of A starts with zeros, so does that row in L
 - when a column of A starts with zeros, so does that column of U

Linear algebra

26

LU factorisation

- U has the pivots on its diagonal whereas L has 1s

- if we write U as
$$\begin{bmatrix} d_1 & & & \\ & d_2 & & \\ & & \ddots & \\ & & & d_n \end{bmatrix} \begin{bmatrix} 1 & u_{12}/d_1 & u_{13}/d_1 & \vdots \\ & 1 & u_{23}/d_2 & \vdots \\ & & \ddots & \vdots \\ & & & 1 \end{bmatrix}$$

we can now write $A=LDU$

- the new upper triangular matrix is also referred to as U
- in this form we assume that each row of U has been divided by its pivot, e.g.:

$$\begin{bmatrix} 2 & 8 \\ 6 & 29 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} 2 & 8 \\ 0 & 5 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} 2 & \\ & 5 \end{bmatrix} \begin{bmatrix} 1 & 4 \\ 0 & 1 \end{bmatrix}$$

Linear algebra

27

One square system = two triangular systems

- the LU decomposition is important in solving $Ax=b$
 - rewrite as $LUx=b$
 - we apply the forward elimination steps of L to b
 - effectively solve $Lc=b$
 - then solve $Ux=c$ by back substitution
- but what have we achieved?

Linear algebra

28

One square system = two triangular systems

Example

Solve the following using an LU decomposition:

$$\begin{bmatrix} 2 & 2 \\ 4 & 9 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} 8 \\ 21 \end{bmatrix}$$

Linear algebra

29

Transposes and permutations

- simple exchange of rows and columns: $(A^T)_{ij} = A_{ji}$
- rules
 - under addition: $(A+B)^T = A^T + B^T$
 - under multiplication: $(AB)^T = B^T A^T$
 - inverses: $(A^{-1})^T = (A^T)^{-1}$

Ax combines the columns of A while $x^T A^T$ combines the rows of A^T – the same combinations of the same vectors

- the transpose of the column Ax is the row $x^T A^T$, thus

$$(Ax)^T = x^T A^T$$

Linear algebra

30

Transposes and permutations

- but what about $(AB)^T$?
 - assume that $B=[x_1 \ x_2]$ has two columns
 - the columns of AB are Ax_1 and Ax_2
 - their transposes are $x_1^T A^T$ and $x_2^T A^T$
 - these are the rows of $B^T A^T$

$$\begin{array}{l} \text{Transposing } AB = \begin{bmatrix} Ax_1 & Ax_2 & \cdots \end{bmatrix} \\ \text{gives } \begin{bmatrix} x_1^T A^T \\ x_2^T A^T \\ \vdots \end{bmatrix} \text{ which is } B^T A^T \end{array}$$

Linear algebra

31

Transposes and permutations

- this rule extends to more than two matrices
 - $(ABC)^T = C^T B^T A^T$
 - if $A=LDU$ then $A^T = U^T D L^T$ – the pivot matrix $D=D^T$

- if we apply this rule to both sides of $A^{-1}A=I$ we get

$$A^T (A^{-1})^T = I$$

and similarly if we do the same with $AA^{-1}=I$ we get

$$(A^{-1})^T A^T = I$$

A^T is invertible exactly when A is invertible and we can swap the order of transposing and inverting

Linear algebra

32

Symmetric matrices

- any matrix where $A^T = A$
 - their inverses are also symmetric
- for any non-symmetric matrix R , both $R^T R$ and $R R^T$ are symmetric – easy to prove
- we can apply elimination to a symmetric matrix
 - the smaller matrices remain symmetric as elimination proceeds

$$\begin{bmatrix} 1 & 2 \\ 2 & 7 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 0 & 3 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} 1 & \\ & 3 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 0 & 1 \end{bmatrix}$$

- and U is the transpose of L and we have that

$$A = LDL^T \quad (LDL^T)^T = (L^T)^T D^T L^T = LDL^T$$

Linear algebra

33

Permutation matrices

- row exchanges, e.g. for a 3x3 matrix

$$I = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \end{bmatrix} \quad P_{21} = \begin{bmatrix} & 1 & \\ 1 & & \\ & & 1 \end{bmatrix} \quad P_{32}P_{21} = \begin{bmatrix} & & 1 \\ 1 & & \\ & 1 & \end{bmatrix}$$

$$P_{31} = \begin{bmatrix} & & 1 \\ & 1 & \\ 1 & & \end{bmatrix} \quad P_{32} = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \end{bmatrix} \quad P_{21}P_{32} = \begin{bmatrix} 1 & & \\ & & 1 \\ 1 & & \end{bmatrix}$$

- P^{-1} is also a permutation matrix
 - the four left matrices above are their own inverse
 - the two right matrices are inverses of each other
 - note that the order is reversed!!!
- $P^{-1} = P^T$
 - the four left matrices above are their own transposes
 - the two right matrices are transposes of each other

Linear algebra

34

LU factorization with row exchange

- row exchanges are sometimes required in order to produce pivots

$$A = (E^{-1} \dots P^{-1} \dots E^{-1} \dots P^{-1} \dots)U$$

- we can combine all permutations into a single P
 - but where do we put it?

- two solutions

- move row exchanges to the left side

- $PA=LU$

- perform row exchanges after elimination

- $A=L_1P_1U_1$

- P_1 puts rows into the right order in U_1

Linear algebra

35

LU factorization with row exchange

- e.g.:
$$\begin{array}{c} \begin{bmatrix} 0 & 1 & 1 \\ 1 & 2 & 1 \\ 2 & 7 & 9 \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 2 & 7 & 9 \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 0 & 3 & 7 \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 4 \end{bmatrix} \\ A \qquad \qquad PA \qquad \qquad \ell_{31}=2 \qquad \qquad \ell_{32}=3 \end{array}$$

the matrix is now in good order and it factorises as follows

$$PA = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 4 \end{bmatrix} = LU$$

so long as A is invertible

Linear algebra

36

Vector spaces and subspaces

- columns of Ax and AB are linear combinations of n vectors
 - the columns of A
 - vector spaces and subspaces
- most simple examples are $\mathbb{R}^1, \mathbb{R}^2, \mathbb{R}^3$, etc
 - \mathbb{R}^n : n -dimensional space
 - all column vectors v with n components
- rules
 - commutative law: $v + w = w + v$
 - distributive law: $c(v + w) = cv + cw$
 - zero vector: $0 + v = v$

Linear algebra

37

Vector spaces and subspaces

- some other vector spaces
 - M : all real 2 by 2 matrices
 - F : all real functions of $f(x)$
 - Z : consists only of a zero vector
- in all cases additions and multiplications result in new vectors that stay in the vector space

Linear algebra

38

Subspaces

- a subspace of a vector space is a set of vectors that satisfies two requirements
- if v and w are vectors in the subspace and c is any scalar, then
 - $v + w$ is in the subspace
 - cv is in the subspace
- all linear combinations stay in the subspace
- every subspace contains the zero vector

Linear algebra

39

Subspaces

- planes that don't contain the origin are not subspaces
 - i.e. for v on such a plane, $-v$ & $0v$ are not on the plane
- keeping only parts of the subspace violate the conditions
 - e.g. keeping only vectors (x,y) where $x \& y > 0$
 - e.g. even if we include (x,y) where $x \& y < 0$
- a subspace containing v and w contain all linear combinations of $cv + dw$

Linear algebra

40

The column space of A

- we are interested in subspaces associated with $Ax = b$
- when A is not invertible the system is solvable for some b but not for others
 - it is solvable only when b is in the column space of A
- the column space of A contains all linear combinations of its columns – all possible combinations Ax
- the columns of an $m \times n$ matrix A have m components
 - the set of all column combinations Ax are a subspace
 - the column space is a subspace of \mathbb{R}^m

Linear algebra

41

The column space of A

Example

$$Ax = \begin{bmatrix} 1 & 0 \\ 4 & 3 \\ 2 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = b \quad \text{which is} \quad x_1 \begin{bmatrix} 1 \\ 4 \\ 2 \end{bmatrix} + x_2 \begin{bmatrix} 0 \\ 3 \\ 3 \end{bmatrix} = b$$

- the column combinations fill up the column space which is in \mathbb{R}^3
 - the column space is actually a subspace of \mathbb{R}^3
- if the right side b lies on that plane then it is one of those combinations and the corresponding (x_1, x_2) is a solution
- if the right side is not on the plane then there is no solution to what are 3 equations in 2 unknowns
- the column space is denoted by $C(A)$

Linear algebra

42

The column space of A

$$A = \begin{bmatrix} 1 & 0 \\ 4 & 3 \\ 2 & 3 \end{bmatrix}$$

$$b = x_1 \begin{bmatrix} 1 \\ 4 \\ 2 \end{bmatrix} + x_2 \begin{bmatrix} 0 \\ 3 \\ 3 \end{bmatrix}$$

Linear algebra

43

The column space of A

Example

Describe the column spaces of the following matrices

$$I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad A = \begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix} \quad B = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 0 & 4 \end{bmatrix}$$

but note that there will be more solutions to B than I and A... why?

Linear algebra

44

The nullspace of A

- the nullspace describes the solutions to $Ax = 0$
 - one obvious solution, $x = 0$
 - for invertible matrices it's the only solution
- an $m \times n$ matrix has a nullspace $N(A)$ in \mathbb{R}^n
 - specifically the nullspace is a subspace of \mathbb{R}^n
- if the right side b is not 0 then the solutions of $Ax = b$ do not form a subspace: $x = 0$ is only a solution if $b = 0$
 - when the set of solutions does not include $x = 0$ it cannot be a subspace

Linear algebra

45

The nullspace of A

Example

The equation $x + 2y + 3z = 0$ comes from the matrix

$$A = \begin{bmatrix} 1 & 2 & 3 \end{bmatrix}$$

The equation produces a plane through the origin. This is the nullspace, a subspace of \mathbb{R}^3 .

The solutions to $x + 2y + 3z = 6$ also form a plane, but not a subspace.

Linear algebra

46

The nullspace of A

Example

Describe the nullspace of

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 6 \end{bmatrix}$$

The nullspace $N(A)$ contains all multiples of

$$s = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

so the nullspace is a line.

Do the same for

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 8 \end{bmatrix} \quad B = \begin{bmatrix} A \\ 2A \end{bmatrix} \quad \text{and} \quad C = [A \quad 2A]$$

Linear algebra

47

The nullspace of A

$$C = \begin{bmatrix} 1 & 2 & 2 & 4 \\ 3 & 8 & 6 & 16 \end{bmatrix} \quad \text{becomes} \quad U = \begin{bmatrix} 1 & 2 & 2 & 4 \\ 0 & 2 & 0 & 4 \end{bmatrix}$$

$\uparrow \quad \uparrow \quad \uparrow \quad \uparrow$
 pivot columns free columns

- produce zeros above the pivots by eliminating upwards

$$U = \begin{bmatrix} 1 & 2 & 2 & 4 \\ 0 & 2 & 0 & 4 \end{bmatrix} \quad \text{becomes} \quad R = \begin{bmatrix} 1 & 0 & 2 & 0 \\ 0 & 1 & 0 & 2 \end{bmatrix}$$

$\uparrow \quad \uparrow$
 pivot columns contain 1

- produce ones in the pivots by dividing the whole row by its pivot

$$s_1 = \begin{bmatrix} -2 \\ 0 \\ 1 \\ 0 \end{bmatrix} \quad \text{and} \quad s_2 = \begin{bmatrix} 0 \\ -2 \\ 0 \\ 1 \end{bmatrix}$$

\leftarrow pivot variables
 \leftarrow free variables

- the r.h.s is not changed – it's all zero!
 - nullspace stays the same

Linear algebra

48

The nullspace of A

- to describe the nullspace we determine the special solutions to $Ax = 0$
 - $N(A)$ contains all combinations of the special solutions
- when the only solution to $Ax = 0$ is $x = 0$, the nullspace contains only that special vector $x = 0$
 - the zero or trivial combination
 - the nullspace is \mathbf{Z}
 - this tells us that the columns of A are independent
 - no combination of columns gives us the zero vector except the zero combination

Linear algebra

49

Solving $Ax = 0$ by elimination

- involves:
 - forward elimination from $A \rightarrow U \rightarrow R$
 - backward substitution in $Ux = 0$ or $Rx = 0$ to find x
- there may not be n pivots, e.g.

$$A = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 2 & 2 & 8 & 10 \\ 3 & 3 & 10 & 13 \end{bmatrix} \text{ becomes } U = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 0 & 4 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

there are four unknowns and only two pivots so there are infinitely many solutions – but how to describe them?

- pivot variables and free variables

Linear algebra

50

Solving $Ax = 0$ by elimination

$$x = x_2 \underbrace{\begin{bmatrix} -1 \\ 1 \\ 0 \\ 0 \end{bmatrix}}_{\text{special}} + x_4 \underbrace{\begin{bmatrix} -1 \\ 0 \\ -1 \\ 1 \end{bmatrix}}_{\text{special}} = \underbrace{\begin{bmatrix} -x_2 - x_4 \\ x_2 \\ -x_4 \\ x_4 \end{bmatrix}}_{\text{complete}}$$

- P : the pivot variables are x_1 and x_3
- F : the free variables are x_2 and x_4
- these solve $Ux=0$ and therefore $Ax=0$
- every solution is
 - a combination of the special solution
 - in the nullspace $N(A)$
- the combinations fill out the nullspace

Linear algebra

51

Echelon matrices

$$U = \begin{bmatrix} x & x & x & x & x & x & x \\ 0 & x & x & x & x & x & x \\ 0 & 0 & 0 & 0 & 0 & x & x \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

3 pivot variables x_1, x_2, x_6

4 free variables x_3, x_4, x_5, x_7

four special solutions in $N(U)$

- what are the column and nullspaces?
- if A has more columns than rows ($n > m$)
 - there at most m pivots
 - there is at least 1 free variable
 - $Ax = 0$ has at least one special solution – not $x = 0$
- the number of free variables dictates the dimension of the nullspace – a subspace

Linear algebra

52

The reduced Echelon matrix, R

$$U = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 0 & 4 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix} \text{ becomes } R = \begin{bmatrix} 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

- if A is invertible then $R = I$
- zeros in R make it easy to find the special solutions
 - the nullspace $N(A) = N(U) = N(R)$

$$x = x_2 \begin{bmatrix} -1 \\ 1 \\ 0 \\ 0 \end{bmatrix} + x_4 \begin{bmatrix} -1 \\ 0 \\ -1 \\ 1 \end{bmatrix} \text{ as before}$$

Linear algebra

53

The rank and row reduced echelon form

- R can be obtained from an elimination matrix: $EA = R$
 - square matrix E is the product of the elementary matrices, E_{ij} , P_{ij} and D^{-1}
 - E is obtained from row reduction on $[A \ I]$ since

$$E[A \ I] = [R \ E]$$
 - which is Gauss-Jordan elimination
- when A is square and invertible, $EA = R = I$
 - E is then A^{-1}
- here we consider all (rectangular) matrices
 - E will obtain R , but R will not necessarily equal I
 - it shows us the pivot columns and special solutions

Linear algebra

54

The rank of a matrix

- reflects the true size of the linear system
- the rank is equal to the number of pivots, r
 - $r \leq m$ and $r \leq n$
 - when $r = m$ the matrix is of full row rank
 - no zero rows in R
 - when $r = n$ the matrix is of full column rank
 - no free variables
- a square, invertible matrix has $r = m = n$ and $R = I$
- at higher levels
 - the matrix has r independent rows and columns
 - r is the dimension of the row and column space

Linear algebra

55

The pivot columns

- pivots in R are all 1
 - respective columns form an I matrix which is $r \times r$

$$A = \begin{bmatrix} 1 & 3 & 0 & 2 & -1 \\ 0 & 0 & 1 & 4 & -3 \\ 1 & 3 & 1 & 6 & -4 \end{bmatrix} \text{ becomes } R = \begin{bmatrix} 1 & 3 & 0 & 2 & -1 \\ 0 & 0 & 1 & 4 & -3 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

- for this example

$$E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -1 & -1 & 1 \end{bmatrix} \text{ and } E^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}$$

the r pivot columns of A are the first r columns of E^{-1}

- $A = E^{-1}R$: each column of A is E^{-1} times a column of R
- 1's in the pivots of R pick out first r columns of E^{-1}

Linear algebra

56

The pivot columns

- pivot columns are **not** combinations of earlier columns
 - clearly true for R and also true for A
 - since $Ax = 0$ exactly when $Rx = 0$
 - solutions do not change during elimination
- free columns **are** combinations of earlier columns
 - the combinations are given exactly by the special solutions

Linear algebra

57

Special solutions

- special solutions have one free variable equal to 1
 - all others are zero
- special solutions can be read off directly from R to give the nullspace matrix N

$$Rx = \begin{bmatrix} 1 & 3 & 0 & 2 & -1 \\ 0 & 0 & 1 & 4 & -3 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \quad N = \begin{bmatrix} -3 & -2 & 1 \\ 1 & 0 & 0 \\ 0 & -4 & 3 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{matrix} \text{not free} \\ \text{free} \\ \text{not free} \\ \text{free} \\ \text{free} \end{matrix}$$

which gives the full solution to $Ax = 0$ (and $Rx = 0$)

- note once again the presence of the I matrix

Linear algebra

58

Special solutions

- there is a special solution for each free variable
 - with r pivot columns there are $n - r$ free variables
 - free solutions are independent

- for $Ax = 0$
 - n unknowns
 - r independent equations
 - $n - r$ independent solutions

- in the case where the first r columns are pivot columns

$$R = \begin{bmatrix} I & F \\ 0 & 0 \end{bmatrix} \quad \begin{array}{l} r \text{ pivot rows} \\ m-r \text{ zero rows} \end{array} \quad N = \begin{bmatrix} -F \\ I \end{bmatrix} \quad \begin{array}{l} r \text{ pivot variables} \\ n-r \text{ free variables} \end{array}$$

r pivot columns $n-r$ free columns

Linear algebra

59

Special solutions

- and note that $RN = \begin{bmatrix} I & F \\ 0 & 0 \end{bmatrix} \begin{bmatrix} -F \\ I \end{bmatrix} = I(-F) + FI = 0$

- the columns of N solve $Rx = Ax = 0$
- pivot variables come by changing signs (F to $-F$) in the free columns of R

$$I \begin{bmatrix} \text{pivot} \\ \text{variables} \end{bmatrix} = -F \begin{bmatrix} \text{free} \\ \text{variables} \end{bmatrix}$$

- in each special solution the free variables are a column of I
- then the pivot variables are a column of $-F$
- they give the nullspace matrix N

Linear algebra

60

Special solutions

- this holds irrespective of the order of the pivot and free columns
- also note that no matter what method we use to reduce A we always obtain the same R

Example: The special solutions of $x_1 + 2x_2 + 3x_3 = 0$ are

$$N = \begin{bmatrix} -2 & -3 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}$$

and the coefficient matrix is $[1 \ 2 \ 3] = [I \ F]$. The rank is 1 so there are $n - r = 2$ special solutions in N . Their first components are $-F = [-2 \ -3]$. The other free variables come from I .

Linear algebra

61

The complete solution to $Ax = b$

$$\begin{bmatrix} 1 & 3 & 0 & 2 \\ 0 & 0 & 1 & 4 \\ 1 & 3 & 1 & 6 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 1 \\ 6 \\ 7 \end{bmatrix} \quad \text{has the augmented matrix} \quad \begin{bmatrix} 1 & 3 & 0 & 2 & 1 \\ 0 & 0 & 1 & 4 & 6 \\ 1 & 3 & 1 & 6 & 7 \end{bmatrix} = [A \ b]$$

$$\begin{bmatrix} 1 & 3 & 0 & 2 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 1 \\ 6 \\ 0 \end{bmatrix} \quad \text{has the augmented matrix} \quad \begin{bmatrix} 1 & 3 & 0 & 2 & 1 \\ 0 & 0 & 1 & 4 & 6 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} = [R \ d]$$

- $x_2 = x_4 = 0$ are free variables, $x_1 = 1$ and $x_3 = 6$ are pivot variables taken from d , giving the particular solution $x_p = [1 \ 0 \ 6 \ 0]^T$

$$\begin{bmatrix} 1 & 3 & 0 & 2 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 6 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 6 \\ 0 \end{bmatrix} \quad \begin{array}{l} \text{Pivot variables } 1, 6 \\ \text{Free variables } 0, 0 \end{array}$$

Linear algebra

62

The complete solution to $Ax = b$

$$\begin{bmatrix} 1 & 3 & 0 & 2 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 6 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 6 \\ 0 \end{bmatrix}$$

Pivot variables 1,6
Free variables 0, 0

- $x_2 = x_4 = 0$ are free variables, $x_1 = 1$ and $x_3 = 6$ are pivot variables taken from d , giving $x_p = (1, 0, 6, 0)$
 - after row reduction we solve $Rx = d$
 - the particular solution solves $Ax_p = b$
 - the $n - r$ special solutions solve $Ax_n = 0$

Linear algebra

63

The complete solution to $Ax = b$

- given a square invertible matrix, what are x_p and x_n ?
 - the particular solution is $A^{-1}b$
 - there are no special solutions – no free variables
 - the null space contains only the zero vector
 - the complete solution is $x = x_p + x_n = A^{-1}b + 0$
 - solution $A^{-1}b$ appears in the extra column
 - the reduced form of A is $R = I$
 - in this case $[A \ b]$ is reduced to $[I \ A^{-1}b]$
 - $Ax = b$ is reduced all the way to $x = A^{-1}b$

Linear algebra

64

The complete solution to $Ax = b$

Example: Find the condition on (b_1, b_2, b_3) for $Ax = b$ to be solveable if:

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ -2 & -3 \end{bmatrix} \quad \text{and} \quad b = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}$$

This condition puts b in the column space of A . Find the complete $x = x_p + x_n$.

A has full column rank $r = n$

— here

$$R = \begin{bmatrix} n \text{ by } n \text{ identity matrix} \\ m - n \text{ rows of zeros} \end{bmatrix} = \begin{bmatrix} I \\ 0 \end{bmatrix}$$

there are no free variables — F is empty

Linear algebra

65

The complete solution to $Ax = b$

- for every matrix A of full column rank ($m \geq n = r$)
 - all columns of A are pivot columns
 - there are no free variables or special solutions
 - $N(A)$ contains only $x = 0$
 - if $Ax = b$ has a solution it is unique
- we will also see that
 - A has independent columns
 - $A^T A$ is invertible
 - there will be $m - n$ zero rows in R
 - there will be $m - n$ conditions on b in order to have $0 = 0$ in those rows

Linear algebra

66

The complete solution to $Ax = b$

- for every matrix A of full row rank ($r = m \leq n$)
 - all rows of A have pivots and R has no zero rows
 - $Ax = b$ has a solution for any right side b
 - the column space is the whole space \mathbb{R}^m
 - there are $n - r = n - m$ special solutions in the nullspace of A
 - the rows are linearly independent

Linear algebra

67

The complete solution to $Ax = b$

- **Example:** The following system has $n = 3$ unknowns but only two equations. The rank is $r = m = 2$.

$$\begin{aligned} x + y + z &= 3 \\ x + 2y - z &= 4 \end{aligned}$$

Show that the complete solution is given by

$$x = x_p + x_n = \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix} + x_3 \begin{bmatrix} -3 \\ 2 \\ 1 \end{bmatrix}$$

Linear algebra

68

The complete solution to $Ax = b$

- four possibilities depending on the rank
 - $r = m$ and $r = n$: square and invertible, 1 solution
 - $r = m$ and $r < n$: short and wide, infinite solutions
 - $r < m$ and $r = n$: tall and thin, 0 or 1 solution
 - $r < m$ and $r < n$: unknown shape, 0 or infinite solutions
- R will fall into the same category as A
- with the pivot columns first

$$R = \begin{bmatrix} I & F \\ 0 & 0 \end{bmatrix}$$

Linear algebra

69

Linear independence

- the columns of A are linearly independent when the only solution to $Ax = 0$ is $x = 0$
 - no other combination Ax gives the zero vector
 - $N(A)$ contains only the zero vector
- the sequence of vectors v_1, v_2, \dots, v_n is linearly independent if the only combination that gives the zero vector is $0v_1 + 0v_2 + \dots + 0v_n$

Linear algebra

70

Linear independence

Example: Determine whether the columns of A are independent or dependent if we know that:

$$Ax = \begin{bmatrix} 1 & 0 & 3 \\ 2 & 1 & 5 \\ 1 & 0 & 3 \end{bmatrix} \begin{bmatrix} -3 \\ 1 \\ 1 \end{bmatrix} = 0$$

Linear algebra

71

Linear independence

- the columns of A are independent exactly when $r = n$
 - there are n pivots
 - only $x = 0$ is in the nullspace
- for square matrices independent columns imply independent rows
- any set of n vectors in \mathbf{R}^m must be linearly dependent for $n > m$, then $Ax = 0$ will have a nonzero solution

Linear algebra

72

Vectors that span a subspace

- combinations of the columns, Ax , span the column space
 - the column space is spanned by the columns
 - $C(A)$ is a subspace of \mathbb{R}^m
- a set of vectors spans a space if their linear combinations fill the space
- combinations of the rows of A span the row space
 - $C(A^T)$ is a subspace of \mathbb{R}^n

Linear algebra

73

Vectors that span a subspace

Example: the column space of A is spanned by the two columns of A – a plane in \mathbb{R}^3 . The row space is spanned by the three rows of A – all of \mathbb{R}^2 .

$$A = \begin{bmatrix} 1 & 4 \\ 2 & 7 \\ 3 & 5 \end{bmatrix} \quad m = 3 \quad \text{and} \quad n = 2$$

Linear algebra

74

A basis for a vector space

- two properties
 - the vectors are linearly independent
 - the vectors span the space
- every vector in the vector space is a combination of the basis vectors
- the standard bases for \mathbb{R}^n come from the n by n identity matrix I – but they are not the only possibilities
 - the columns of any invertible n by n matrix give a valid basis

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{or} \quad \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}$$

Linear algebra

75

A basis for a vector space

- when A is invertible its columns are independent
 - only solution to $Ax = 0$ is $x = 0$
 - columns span the whole space \mathbb{R}^n because every vector b is a combination of the columns
 - $Ax = b$ can always be solved by $x = A^{-1}b$
- the vectors v_1, \dots, v_n are a basis for \mathbb{R}^n exactly when they are the columns of an n by n invertible matrix
 - \mathbb{R}^n has infinitely many bases
- the pivot columns of A are a basis for its column space
- the pivot rows of A are a basis for its row space

Linear algebra

76

A basis for a vector space

Example: Reduce A to R and then find and compare bases for their column and row spaces.

$$A = \begin{bmatrix} 2 & 4 \\ 3 & 6 \end{bmatrix}$$

Example: Find a basis for the column space of

$$R = \begin{bmatrix} 1 & 2 & 0 & 3 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

Example: How would you find a basis for the space spanned by five vectors in \mathbb{R}^7 ?

N.B. the differences between the column spaces of A and R !!!

Linear algebra

77

Dimension of a vector space

- all the different bases for the same space have the same number of vectors – this is the dimension of the space
- if v_1, \dots, v_m and w_1, \dots, w_n are two bases for the same space, then $m = n$

– w_1 must be a combination of the v 's

– if $w_1 = a_{11}v_1 + \dots + a_{m1}v_m$ – the first column of a matrix multiplication

$$W = \begin{bmatrix} w_1 & w_2 & \dots & w_n \end{bmatrix} = \begin{bmatrix} v_1 & v_2 & \dots & v_m \end{bmatrix} \begin{bmatrix} a_{11} & a_{1n} \\ \vdots & \vdots \\ a_{m1} & a_{mn} \end{bmatrix} = VA$$

– we don't know each a_{ij} but we know that A is m by n

Linear algebra

78

Dimension of a vector space

- A has a row for every v and a column for every w
 - if we assume that $n > m$ it is a short, wide $m \times n$ matrix
 - there is a nonzero solution to $Ax = 0$
 - then $VAx = 0$ and $Wx = 0$
 - a combination of the w 's gives zero
 - columns of W cannot be a basis
 - same outcome if we consider $m > n$,
 - therefore m must equal n
- the dimension of a vector space is the number of vectors in every basis
- the dimension of the column space is the rank of the matrix

Linear algebra

79

Bases for matrix spaces and function spaces

- not just column vectors – matrices and functions too!
- all 2 by 2 matrices might have bases

$$A_1, A_2, A_3, A_4 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$$

bases easily found for e.g. all diagonal, all upper triangular matrices, or all symmetric matrices etc.

Linear algebra

80

Dimensions of the four subspaces

- the rank of a matrix defines the dimension of all four subspaces
 - two subspaces from A , two from A^T
- row space $C(A^T)$ a subspace of \mathbb{R}^n
 - also the column space of A^T
- column space $C(A)$ a subspace of \mathbb{R}^m
- nullspace $N(A)$ a subspace of \mathbb{R}^n
- left nullspace $N(A^T)$ a subspace of \mathbb{R}^m
 - nullspace of A^T – obtained by solving $A^T y = 0$
 - an $n \times m$ system
 - vectors y go on the left when written as $y^T A = 0^T$
- all of these spaces are connected

Linear algebra

81

Dimensions of the four subspaces

- we will learn about two fundamental theorems of linear algebra
- Fundamental Theorem 1
 - the column space and the row space have the same dimension r – the rank of the matrix A
 - the two nullspaces have dimensions $n-r$ and $m-r$
 - they make up the full dimensions n and m
- Fundamental Theorem 2
 - we will see how these four subspaces fit together

Linear algebra

82

Dimensions of the four subspaces

- we can reduce A to its row echelon form R
 - the dimensions of the four subspaces are the same for both A and R

Linear algebra

83

Dimensions of the four subspaces

Example

Take a matrix R , where $m = 3$, $n = 5$ and $r = 2$

$$R = \begin{bmatrix} 1 & 3 & 5 & 0 & 9 \\ 0 & 0 & 0 & 1 & 8 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad \begin{array}{l} \text{pivot rows 1 and 2} \\ \text{pivot columns 1 and 4} \end{array}$$

- the rank of R is $r = 2$
- the row space of R has dimension r
 - pivot rows 1 and 2 span the row space, they are independent and form a basis

Linear algebra

84

Dimensions of the four subspaces

...example (cont.)

- the column space of R has dimension r
 - pivot columns 1 and 4 span the column space, they are independent and form a basis
 - $c_2 = 3c_1$: special solution is $s_2 = (-3, 1, 0, 0, 0)^T$
 - $c_3 = 5c_1$: special solution is $s_3 = (-5, 0, 1, 0, 0)^T$
 - $c_5 = 9c_1 + 8c_4$: special solution is $s_5 = (-9, 0, 0, -8, 1)^T$

Linear algebra

85

Dimensions of the four subspaces

...example (cont.)

- the nullspace has dimension $n - r = 5 - 2 = 3$
 - there are no pivots in columns 2, 3 and 5
 - these three free variables lead to the three special solutions to $Rx = 0$ which are independent and form a basis
 - we have the same special solutions as before
 - $Rx = 0$ has the complete solution $x = x_2s_2 + x_3s_3 + x_5s_5$
 - the pivot variables x_1 and x_4 are totally determined by $Rx = 0$

Linear algebra

86

Dimensions of the four subspaces

...example (cont.)

- the nullspace of R^T has dimension $m - r = 3 - 2 = 1$
- $R^T y = 0$ looks for combinations of the columns of R^T that produce 0:
 - $y_1(1,3,5,0,9) + y_2(0,0,0,1,8) + y_3(0,0,0,0,0) = (0,0,0,0,0)$
- the nullspace thus contains all vectors in $(0,0,y_3)$
 - it is the line of all multiples of the basis vector $(0,0,1)$
- in \mathbb{R}^n the row space and nullspace have dimensions r and $n - r$ (the two add to n)
- in \mathbb{R}^m the column space and the left nullspace have dimension r and $m - r$ (the two add to m)

Linear algebra

87

Dimensions of the four subspaces

Linear algebra

88

Dimensions of the four subspaces

- A and R have the same subspace dimensions
 - they are connected according to $EA = R$ and $A = E^{-1}R$
- A has the same row space, dimension and basis as R
 - every row of A is a combination of the rows of R
 - every row of R is a combination of the rows of A
- the column spaces of A and R have the same dimension
 - but the column spaces are NOT the same!
 - $Ax = 0$ when $Rx = 0$ – same combination of columns
 - r pivot columns of A are the basis for its column space
 - r pivot columns of R are the basis for its column space

Linear algebra

89

Dimensions of the four subspaces

- A has the same nullspace, dimension and basis as R
 - elimination doesn't change the solutions
 - the special solutions are a basis for this nullspace
 - there are $n - r$ free variables, so the dimension is $n - r$
- the left nullspace of A has dimension $m - r$
 - if we know the dimensions of A then we know them for A^T
 - A^T is $n \times m$ so the “whole space” is now \mathbb{R}^m
 - $r + (m - r) = m$

Linear algebra

90

1st Fundamental Theorem of Linear Algebra

the column space and row space both have dimension r

$$C(A) = C(A^T) = r$$

the nullspaces have dimensions $n - r$ and $m - r$

$$N(A) = n - r \quad \text{and} \quad N(A^T) = m - r$$

1st Fundamental Theorem of Linear Algebra

Example

Describe the spaces of

$$A = \begin{bmatrix} 1 & 2 & 3 \end{bmatrix} \quad \text{and} \quad A = \begin{bmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{bmatrix}$$
